Breathable Absorbent Articles

10

15

Field of the Invention

The present invention relates to absorbent articles in particular sanitary napkins with improved comfort, particularly by the use of breathable backsheets whilst maintaining protection level performance.

Background of the Invention

The primary consumer needs which underlie development in the absorbent article field, in particular catamenials is the provision of products providing both a high protection and comfort level.

One means for providing consumer comfort benefits in absorbent articles is by the provision of breathable products. Breathability has typically concentrated on the incorporation of so called 'breathable backsheets' in the absorbent articles. Commonly utilised breathable backsheets are microporous films and apertured formed films having directional fluid transfer as disclosed in for example US 4 591 523. Both these types of breathable backsheets are vapour permeable allowing gaseous exchange with the environment. This thereby allows for the evaporation of a portion of the fluid stored in the core and increases the circulation of air within the absorbent article. The latter is particularly

beneficial as it reduces the sticky feeling experienced by many wearers during use, commonly associated with the presence of an apertured formed film or film like topsheet, particularly over extended periods of time. This is a result of topsheets designed to achieve a clean and dry appearance. These topsheets tend to be smooth thereby minimising the build up of fluid on the surface of the topsheet. However, these benefits are achieved at the expense of comfort, particularly under hot and humid conditions, when due to their smooth surface texture they tend to become sticky to the skin.

10

However, the main drawback associated with the use of breathable backsheets in absorbent articles is the negative effect on the protection level performance, by leakage known as wet through onto the users garment. Although, breathable backsheets in principle only allow the transfer of materials in the gaseous state, physical mechanisms such as extrusion, diffusion and capillary action may still occur and result in the transfer of the fluids from the absorbent core through the backsheet and onto the users garments. In particular, these mechanisms become more dominant if the product is utilised during physical exertion, or for heavy discharge loads or over extended periods of time. Thus, whilst the incorporation of breathable backsheets in absorbent articles is highly desirable from a comfort standpoint, since the primary role of a backsheet still remains the prevention of liquid leakage, such breathable backsheets cannot be satisfactorily incorporated into products.

25

The problem of wet through onto users garments due to the incorporation of such breathable backsheets in absorbent articles has indeed also been recognised in the art. Attempts to solve the problem have mainly resided in the use of multiple layer backsheets such as those illustrated in US 4 31 216. Similarly European patent application no. 710 471 discloses a breathable backsheet comprising an outer layer of a gas permeable, hydrophobic, polymeric fibrous fabric and an inner layer comprising an apertured formed film having directional fluid transport. The backsheet construction preferably has no liquid transport/wet through under certain specified test conditions. Also European patent application no. 710 472 discloses a breathable backsheet consisting of at least two breathable layers which are unattached to one another over the core area.

35

The backsheet construction preferably has no liquid transport/wet through under certain specified test conditions.

US 4 713 068 discloses a breathable clothlike barrier for use as an
5 outer cover for absorbent articles. The barrier comprises at least 2 layers, a first layer having a specified basis weight, fibre diameter and pore size and a second layer comprising a continuous film of poly (vinyl alcohol) having a specified thickness. The barrier also has a specified water vapour transmission rate and level of impermeability.

10

However, none of the above proposed solutions have been able to provide a fully satisfactory solution to the problem of breathable backsheet wet through under all conditions. Furthermore, another problem associated with the exemplified multi layer backsheets is an increase in total thickness
15 of the product and a reduction in the flexibility, both of which result in a consumer noticeable reduction in product comfort.

An alternative proposed solution to the problem of breathable backsheet wet through relates to the improvement of the absorbent
20 material such that little or no liquid comes into contact with the backsheet, thereby preventing wet through. This is typically achieved by increasing the amount of absorbent material in the article. However, this results in an absorbent article which is extremely thick which is highly undesirable from a consumer comfort standpoint. Hence, the absorbent article whilst having
25 the required protection level and still maintaining some comfort benefits by the presence of the breathable backsheet, suffers from a lack of comfort from a different source, in this case the increased dimensions of the article.

In addition the above solution also results in a reduction in the
30 flexibility of the article, particularly evident as an increase in the cross section stiffness. It is however also well established that in order to be comfortable for the wearer absorbent articles need to be cross sectionally flexible. It is believed that the more cross sectionally flexible an absorbent article is, the less will it be noticeable to the wearer. Thus flexibility is
35 another highly desirable comfort requirement of modern absorbent articles.

EPO 705 583 and EPO 705 584 propose longitudinally flexible absorbent articles which are vapour permeable. However, the exemplified absorbent articles are typically very thin and do not address the absorbency capacity of the article or the problem of wet through.

5

Thus it not currently possible to provide a comfort improvement to absorbent articles such as by the incorporation of breathable backsheet, without negatively impacting protection levels. In the alternative, if the result protection level problem is then addressed either by multi layered backsheet or increased thickness of the core, there is a further negative impact on the comfort level of the article and vice versa.

10

Consequently, as the incorporation of breathable backsheets in absorbent articles results in reduction of the protection level, further desirable product comfort modifications such as reducing the thickness of the product and improving the flexibility of the product which would furtheracerbate the problem may not be incorporated in the absorbent article.

15

Thus, there exists a dichotomy in the means available to provide increased consumer comfort in absorbent products and acceptable protection levels. It is therefore an objective of the present invention to provide an absorbent article having improved comfort which maintains an acceptable level of protection.

20

It has now been found that this objective may be achieved by the provision of an article whose individual elements must meet certain key functional parameter criteria in terms of comfort provision and/or protection such as the backsheet wet through/liquid permeability, the topsheet dryness, the core caliper and core vapour or vapour/air permeability. Furthermore, these elements are combined such that the resultant product, in addition to these individual elements, meets overall criteria such that it has a certain dryness index and sensory index. The present invention has identified the key components which affect the principle comfort requirements of flexibility, breathability, dryness and caliper and the key components of protection such as liquid retention/wet through and rewet. Surprisingly, it has been found that the specific combination of these components, provides an article delivering both high protection levels as

25

30

35

well as high comfort to the consumer. In particular it is believed that breathability must be considered in terms of total article breathability in addition to the backsheet breathability in order to provide a truly breathable product.

5

A further advantage of the present invention is that one individual low performing component of the absorbent article in terms of rewet, wet through or caliper, but still within the component range, may be compensated by the high performance of another component provided that the overall product criteria are still met.

10

According to the present invention, each component layer is joined so as to minimise the impact on the product criteria parameters. Thus, a further aspect of the present invention relates to the method of manufacture of the absorbent article.

15

Summary of the Invention

The present invention relates to a disposable absorbent article comprising the following elements:

20

a liquid pervious topsheet, an absorbent core and a breathable backsheet, said absorbent core being positioned intermediate said topsheet and said backsheet, said topsheet, core and backsheet each comprising at least one layer. The topsheet has a liquid retention of less than 0.22g for a 2.0g load in the topsheet liquid retention test. The core has a caliper of less than 12mm and has a vapour permeability of at least 200g/m²/24hrs. as defined in the vapour permeability test. The breathable backsheet has a liquid permeability of less than 0.16g for a 15ml. load as defined in the liquid permeability test. The elements are joined such that said absorbent article has a dryness index of greater than 0.5 and a sensory index of greater than 50.

25

30

35

Detailed Description of the Invention

The present invention relates to absorbent disposable articles such as sanitary napkins, panty liners, incontinence products and baby diapers. Typically such products comprise the elements of a liquid pervious topsheet, a backsheet and an absorbent core intermediate said topsheet and said backsheet. According to the present invention the topsheet, backsheet and core may be selected from any of the known types of these components provided that they meet certain comfort and protection performance requirements detailed herein. In particular, the key performance criteria have been identified as; the topsheet liquid retention performance which gives an indication of the ability of the topsheet to maintain a dry surface and thereby keep the skin of the wearer dry; the permeability of the absorbent core and its thickness which relate to the absorbent capacity of the core and its ability to allow the flow of vapour and/or air through it and the backsheet wet through/liquid permeability which indicates the ability of the breathable backsheet to retain the absorbed fluid. Furthermore, the individual elements are joined, preferably utilising optimised joining techniques such that the final product also meets specific comfort and performance level criteria also described herein.

Absorbent article components

The topsheet

According to the present invention the absorbent article comprises as an essential component a topsheet. The topsheets suitable for use herein may be any topsheet known in the art.

The topsheets for use herein may comprise a single layer or a multiplicity of layers. In a preferred embodiment the topsheet comprises a first layer which provides the user facing surface of the topsheet and a second layer between the first layer and the absorbent structure/core. The topsheet typically extends across the whole of the absorbent structure and can extend into and form part of or all of the preferred sideflaps, side wrapping elements or wings.

The topsheet as a whole and hence each layer individually needs to be compliant, soft feeling, and non-irritating to the wearer's skin. It also can

have elastic characteristics allowing it to be stretched in one or two directions. As used herein the topsheet hence refers to any layer or combination of layers whose principle function is the acquisition and transport of fluid from the wearer towards the absorbent core.

5 According to the present invention the topsheet may be formed from any of the materials available for this purpose and known in the art, such as non wovens fabrics, films or combinations of both. In a preferred embodiment of the present invention at least one of the layers of the
10 topsheet comprises a liquid permeable apertured polymeric film. Preferably, the upper layer is provided by a film material having apertures which are provided to facilitate liquid transport from the wearer facing surface towards the absorbent structure, as detailed for example in US 3 929 135, US 4 151 240, US 4 319 868, US 4 324 426, US 4 343 314 and
15 US 4 591 523.

According to the present invention the topsheets suitable for use herein must have a topsheet liquid retention of less than 0.22g, preferably less than 0.15g, more preferably less than 0.1g, most preferably 0g, as
20 defined in the liquid retention test disclosed herein after.

Backsheet

The absorbent article according to the present invention also
25 comprises a breathable backsheet. The backsheet primarily prevents the extrudes absorbed and contained in the absorbent structure from wetting articles that contact the absorbent product such as underpants, pants, pyjamas and undergarments thereby acting as a barrier to fluid transport. In addition however, the breathable backsheet of the present invention
30 permits the transfer of at least vapour, preferably both vapour and air through it and thus allows the circulation of gases into and out of the backsheet. The backsheet typically extends across the whole of the absorbent structure and can extend into and form part of or all sideflaps, side wrapping elements or wings.

35 According to the present invention any known breathable backsheet or multiple layer breathable backsheet composite may be used in the

absorbent article provided that the backsheet meets the requirement of the liquid permeability test as defined herein. The breathable backsheets of the present invention have a liquid permeability at 15ml. load of less than 0.16g, preferably of less than 0.10g, more preferably 0g.

5

According to the present invention suitable breathable backsheets for use herein comprise at least one gas permeable layer. Suitable gas permeable layers include 2 dimensional, planar micro and macro-porous films, macroscopically expanded films, formed apertured films and
10 monolithic films. According to the present invention the apertures in said layer may be of any configuration, but are preferably spherical or oblong and may also be of varying dimensions. The apertures preferably are evenly distributed across the entire surface of the layer, however layers having only certain regions of the surface having apertures are also
15 envisioned.

Suitable 2 dimensional planar layers of the backsheet may be made of any material known in the art, but are preferably manufactured from commonly available polymeric materials. Suitable materials are for example
20 Gortex (TM) or Sympatex (TM) type materials well known in the art for their application in so-called breathable clothing. Other suitable materials include XMP-1001 of Minnesota Mining and Manufacturing Company, St. Paul, Minnesota, USA and Exxair XBF-101W, supplied by the Exxon Chemical Company. As used herein the term 2 dimensional planar layer
25 refers to layers having a depth of less than 1mm, preferably less than 0.5mm, wherein the apertures have an average uniform diameter along their length and which do not protrude out of the plane of the layer. The apertured materials for use as a backsheet in the present invention may be produced using any of the methods known in the art such as described in
30 EPO 293 482 and the references therein. In addition the dimensions of the apertures produced by this method may be increased by applying a force across the plane of the backsheet layer (i.e. stretching the layer).

Suitable apertured formed films include films which have discrete
35 apertures which extend beyond the horizontal plane of the garment facing surface of the layer towards the core thereby forming protuberances. The protuberances have an orifice located at its terminating end. Preferably

said protuberances are of a funnel shape, similar to those described in US 3, 929,135. The apertures located within the plane and the orifices located at the terminating end of protuberance themselves maybe circular or non circular provided the cross sectional dimension or area of the orifice at the
5 termination of the protuberance is smaller than the cross sectional dimension or area of the aperture located within the garment facing surface of the layer. Preferably said apertured preformed films are uni directional such that they have at least substantially, if not complete one directional fluid transport towards the core.

10

Suitable macroscopically expanded films for use herein include films as described in for example in US 4 637 819 and US 4 591 523.

Suitable monolithic films include HytreL, available from DuPont
15 Corporation, USA, and other such materials as described in Index 93 Congress, Session 7A "Adding value to Nonwovens", J-C. Cardinal and Y. Trouilhet, DuPont de Nemours international S.A, Switzerland.

Preferred breathable backsheets for use herein are those having a
20 high vapour exchange, most preferably both a high vapour and high air exchange.

Absorbent core

25 According to the present invention the absorbent cores suitable for use in herein may be selected from any of the absorbent cores or core system known in the art provided that certain requirements as concerns caliper and vapour and/or air permeability as defined herein are meet. As used herein the term absorbent core refers to any material or multiple
30 material layers whose primary function is to absorb, store and distribute fluid. The absorbent core of the present invention has a vapour permeability of greater than $500\text{g/m}^2/\text{s}$, preferably greater than $800\text{g/m}^2/24\text{hrs.}$, more preferably $1200\text{g/m}^2/24\text{hrs.}$, most preferably greater than $1500\text{g/m}^2/24\text{hrs.}$ In a preferred embodiment of the present invention
35 the absorbent core also has an air permeability of greater than $200\text{l/m}^2/\text{s}$, more preferably greater than $800\text{l/m}^2/\text{s}$, most preferably greater than $1200\text{l/m}^2/\text{s}$. The absorbent cor thus has a caliper of less than 12mm,

preferably less than 8mm, more preferably less than 5mm, most preferably from 5mm to 2mm.

According to the present invention, the absorbent core can include the following components: (a) an optional primary fluid distribution layer preferably together with a secondary optional fluid distribution layer; (b) a fluid storage layer; (c) an optional fibrous ("dusting") layer underlying the storage layer; and (d) other optional components.

10 a Primary/Secondary Fluid Distribution Layer

One optional component of the absorbent core according to the present invention is a primary fluid distribution layer and a secondary fluid distribution layer. The primary distribution layer typically underlies the topsheet and is in fluid communication therewith. The topsheet transfers the acquired fluid to this primary distribution layer for ultimate distribution to the storage layer. This transfer of fluid through the primary distribution layer occurs not only in the thickness, but also along the length and width directions of the absorbent product. The also optional but preferred secondary distribution layer typically underlies the primary distribution layer and is in fluid communication therewith. The purpose of this secondary distribution layer is to readily acquire fluid from the primary distribution layer and transfer it rapidly to the underlying storage layer. This helps the fluid capacity of the underlying storage layer to be fully utilised. The fluid distribution layers can be comprised of any material typical for such distribution layers.

b Fluid Storage Layer

30 Positioned in fluid communication with, and typically underlying the primary or secondary distribution layers, is a fluid storage layer. The fluid storage layer can comprise any usual absorbent material or combinations thereof. It preferably comprises absorbent gelling materials usually referred to as "hydrogel", "superabsorbent", hydrocolloid" materials in combination with suitable carriers.

The absorbent gelling materials are capable of absorbing large quantities of aqueous body fluids, and are further capable of retaining such absorbed fluids under moderate pressures. The absorbent gelling materials can be dispersed homogeneously or non-homogeneously in a suitable carrier. The suitable carriers, provided they are absorbent as such, can also be used alone.

Suitable absorbent gelling materials for use herein will most often comprise a substantially water-insoluble, slightly cross-linked, partially neutralised, polymeric gelling material. This material forms a hydrogel upon contact with water. Such polymer materials can be prepared from polymerizable, unsaturated, acid-containing monomers which are well known in the art.

Suitable carriers include materials which are conventionally utilised in absorbent structures such as natural, modified or synthetic fibers, particularly modified or non-modified cellulose fibers, in the form of fluff and/or tissues. Suitable carriers can be used together with the absorbent gelling material, however, they can also be used alone or in combinations. Most preferred are tissue or tissue laminates in the context of sanitary napkins and panty liners.

An embodiment of the absorbent structure made according to the present invention comprises a double layer tissue laminate formed by folding the tissue onto itself. These layers can be joined to each other for example by adhesive or by mechanical interlocking or by hydrogen bridge bands. Absorbent gelling material or other optional material can be comprised between the layers.

Modified cellulose fibers such as the stiffened cellulose fibers can also be used. Synthetic fibers can also be used and include those made of cellulose acetate, polyvinyl fluoride, polyvinylidene chloride, acrylics (such as Orlon), polyvinyl acetate, non-soluble polyvinyl alcohol, polyethylene, polypropylene, polyamides (such as nylon), polyesters, bicomponent fibers, tricomponent fibers, mixtures thereof and the like. Preferably, the fiber surfaces are hydrophilic or are treated to be hydrophilic. The storage layer

can also include filler materials, such as Perlite, diatomaceous earth, Vermiculite, etc., to improve liquid retention.

5 If the absorbent gelling material is dispersed non-homogeneously in a carrier, the storage layer can nevertheless be locally homogenous, i.e. have a distribution gradient in one or several directions within the dimensions of the storage layer. Non-homogeneous distribution can also refer to laminates of carriers enclosing absorbent gelling materials partially or fully.

10

c Optional Fibrous ("Dusting") Layer

15 An optional component for inclusion in the absorbent core according to the present invention is a fibrous layer adjacent to, and typically underlying the storage layer. This underlying fibrous layer is typically referred to as a "dusting" layer since it provides a substrate on which to deposit absorbent gelling material in the storage layer during manufacture of the absorbent core. Indeed, in those instances where the absorbent gelling material is in the form of macro structures such as fibers, sheets or strips, this fibrous "dusting" layer need not be included. However, this "dusting" layer provides some additional fluid-handling capabilities such as rapid wicking of fluid along the length of the pad.

20

d Other Optional Components of the absorbent structure

25

The absorbent core according to the present invention can include other optional components normally present in absorbent webs. For example, a reinforcing scrim can be positioned within the respective layers, or between the respective layers, of the absorbent core. Such reinforcing
30 scrims should be of such configuration as to not form interfacial barriers to fluid transfer. Given the structural integrity that usually occurs as a result of thermal bonding, reinforcing scrims are usually not required for thermally bonded absorbent structures.

35

Another component which can be included in the absorbent core according to the invention and preferably is provided close to or as part off the primary or secondary fluid distribution layer are odor control agents.

Absorbent article

5 The potential benefits of incorporating a breathable backsheet into an absorbent structure have been extensively referred to in prior art but, a simple observation of available products in the market places clearly points to a basic failure to realise a benefit in use. In many instances the problem has resulted from an inability to control through breathable backsheet wet-through. According to the present invention the absorbent elements
10 meeting the requirements as described herein above must as an essential requirement be combined such that the resultant absorbent article product meets certain performance and comfort indexes herein referred to as the sensory index and the dryness index. The dryness index is a function of the effective breathability test and rewet test of the absorbent article and
15 the sensory index is a function of the effective breathability test, flexibility and caliper of the absorbent article. The test methods are defined herein after. The indices are defined by the equations below:

20 Dryness index = Effective breathability / (Rewet test)

Sensory index = Effective breathability / (Flexibility * Caliper)

Dryness Index

25 The Dryness Index is a reflection of one of the unexpected interactions that an absorbent article, particularly a sanitary napkin needs to satisfy, in order to provide overall dryness and/or comfort benefits to the wearer of the product. The dryness index reflects that perceived wetness in use is determined by both the dryness of the wearer facing surface
30 of the product that lies closest to the body in use (i.e. absorbent article rewet test) and the dryness that can be achieved via water vapour exchange with the environment and air circulation via the backsheet (i.e. effective breathability).

Effective Breathability:

35 The effective breathability is determined from the equation below:

Effective Breathability = Vapour Permeability + 0.25 x Air Permeability

The effective breathability determines a numerical value for the breathability. It considers the two key mechanisms that are likely to participate in exchange of humidity and temperature while wearing a
5 absorbent article having a breathable backsheet. The first mechanism is water vapour exchange via the process of diffusion. This is a continuous process and the mechanism is well understood and represented by a simple diffusion equation. In addition, body motion can result in a change
10 in the relative position of the wearers body and the absorbent article, for example between a sanitary article and the body known as gapping. This motion also is accompanied by a process of air exchange. Repetitive bodily motion can quite literally pump air into and out of the backsheet or at the sides of the product, where a product may not maintain intimate
15 contact to the body. Naturally the stiffer an absorbent article is in the genital region the less likely is this process of pumping to deliver an additional benefit to simple vapour exchange since the product is less deformable and is likely to press up closer to the body like a gasket.

20 The dryness index provides an indication of the ability of the article to absorb fluids and thus provide protection to the consumer which is given as a function of the permeability of the article and the overall product dryness.

Sensory Index

25 The Sensory Index is an index that quantifies the relationship between product attributes that need to be satisfied in addition to breathability to deliver a true benefit in use. This is due the cross interactions between unexpected product design elements; namely
30 breathability, the product caliper and product stiffness/flexibility.

Thus in short, the sensory index values gives an indication of the range of values of the permeability, flexibility and caliper of the product according to the present invention which provides protection and comfort benefits.

35 According to the present invention the absorb nt article has a s nsory ind x of gr ater than 50, preferably greater than 100, more

15

preferably greater than 200, most preferably greater than 300. The article further has a dryness index of greater than 0.5, preferably greater than 2.0, more preferably greater than 4, most preferably greater than 10.

5 Absorbent article construction

10 A further aspect of the present invention relates to the joining of the topsheet, backsheet and absorbent core elements to provide the absorbent article. According to the present invention at least two, preferably all of the elements of the article are joined.

15 Each of said elements comprising at least one layer has a wearer facing surface and a garment facing surface. Typically, adjacent garment facing surfaces form a common interface with the wearer facing surface of an adjacent element or layer. The elements or layers are joined together across this common interface. In this manner the topsheet is joined to the absorbent core, and the core is joined to the backsheet. Furthermore, each of said topsheet, backsheet and core elements may comprise more than one layer and these layers may also be similarly joined. In addition the
20 topsheet may be directly or indirectly by joined to the backsheet at the periphery of the absorbent article.

25 The elements and layers thereof may be joined by any means known in the art for affixing two adjacent layers of material, such that the layers are directly attached to one another or directly attached to one another via the joining means. Suitable joining means include adhesive, fusion bonding, ultra sonic bonding, stitching, heat (e.g. crimping), embossing, and/or pressure bonds, or dynamic mechanical bonds. According to an embodiment of the present invention the preferred means
30 of joining is adhesive. Suitable adhesives include non pressure sensitive and cold adhesives. The adhesive may be applied by any means known in the art such as spiral application, slot coating, spraying, spiral spraying, curtain coating, control coating and printing, provided that the adhesive does not substantially affect the breathability.

35

 In a preferred embodiment of the present invention the inter element or inter layer joining adhesive is selected and applied so as to reduce any

impact it may have on the effective breathability of the absorbent article and preferably also the flexibility of the absorbent article. In this manner the dryness index and sensory index values may in fact be increased. Since many commonly utilised adhesives are not vapour permeable it is highly preferable to minimise the amount of adhesive used to join the layers/elements of the absorbent article in order to minimise their impact on the permeability (breathability) and preferably also the flexibility of the absorbent article. One means of achieving this is to use particular adhesive application methods such as open adhesive application techniques, whereby areas of the common interface are adhesive free, whilst retaining the required level of attachment/joining of the two adjacent layers or elements. In particular spiral spraying is preferred. The layers and elements should be joined in such a manner so that the absorbent article product maintains structural integrity but no more. This method finds particular application for the interlayer joining of the backsheet element layers and the joining of the backsheet element and the absorbent core element. Alternatively adhesives which are vapour permeable may be used.

Preferably not more than 40%, more preferably less than 20%, most preferably less than 10% of the common interface of two adjacent layers or elements is joined. Furthermore, the density of the adhesive should be reduced and a thin application of adhesive is preferred.

In a preferred embodiment of the present invention wherein the absorbent article finds utility as a sanitary napkin or panty liner, the absorbent article is also provided with a panty fastening means which provides means to attach the article to an undergarment. For example the panty fastening means may comprise a mechanical fastener such as hook and loop fasteners such as marketed under the tradename VELCRO, snaps or holders. Alternatively, the article is fastened to the undergarment by means of panty fastening adhesive on the backsheet. The panty fastening adhesive provides a means for securing the article to the panty and preferably a means for securing the article when soiled, to the fold and wrap package for convenient disposal. Typically, at least a portion of the garment facing surface of the backsheet is coated with adhesive to form the panty fastening adhesive. Any adhesive or glue used in the art for such

purposes can be used for the panty fastening adhesive herein. Pressure sensitive adhesives are most preferred. Suitable adhesives include Century A-305-IV manufactured by the Century Adhesives Corporation of Columbus, Ohio, and Instant LOK 34-2823 manufactured by the National Starch and Chemical Company of Bridgewater, New Jersey, 3 Sigma 3153 manufactured by 3 Sigma and Fuller H-2238ZP manufactured by the H.B. Fuller Co.

The panty fastening adhesive is typically applied to the backsheet by slot coating. In order to reduce the effect of the breathability of the backsheet and thus of the article as a whole, the adhesive is preferably applied such that at least 60%, preferably from at least 80%, most preferably at least 90% of the surface of the backsheet is adhesive free. The required adhesiveness can still be achieved even when using reduced surface coverage by using a particular distribution such as thinner strips, discontinuous strips of adhesive, intermittent dots, random patterns spirals.

The panty fastening adhesive is typically covered with a removable release paper or film in order to prevent the adhesive from drying out or adhering to another surface other than the panty prior to use. Any commercially available release paper or film may be used. Suitable examples include BL 30MG-A SILOX E/O and BL 30 MG-A SILOX 4 P/O available from Akrosil Corporation.

According to the present invention the absorbent article can be used beneficially in the context of sanitary napkins, panty liners, incontinence articles and diapers. However, sanitary napkins are particularly susceptible to the present invention. The disposable article may thus also have all those features and parts which are typical for products in the context of their intended use.

TEST METHODS**Absorbent article component tests****Topsheet Retention test:**

The topsheet retention test is utilised to assess the liquid retention character (of bodily discharges) of topsheet materials or composites that may be used on disposable absorbent articles and particularly sanitary napkins.

Basic Principle of the Methods:

The basic principal of the test is to evaluate the liquid retention behaviour of alternative topsheet materials to liquids that simulate bodily discharges. A "good topsheet material" in this test can be a film (e.g. apertured formed film) or a fibrous or a fibrous nature film provided it has a low propensity to acquiring and retaining liquids either on or within its structure. Naturally a "good topsheet" is also, in addition to having low retention properties expected to allow rapid transmission of bodily discharges further into the article and to hinder discharges that are contained within the article from returning to the upper (body side) surface of the article. Additionally a "good topsheet" should also maintains a clean appearance during use of the articles.

To assess the topsheets retention to liquid, a test is performed as detailed below:

Two sheets (with dimensions of 5 cm x 5 cm) of a commercially available airlayed absorbent tissue each with a basis weight of 63 g/m² available from Walkisoft USA under the supplier code Metmar (P50W.IPED) are utilised to simulate an absorbent core.

A sample of the topsheet material (with dimensions of 5 cm x 5 cm) that is to be assessed is placed directly on top of this absorbent structure. A standardised test liquid closely matching menses in viscosity and electrical conductivity (see below) is dripped onto the centre of the test sample from

a height of 3 cm and at a rate of 2 g/min. until a total of 2 grams has been introduced onto the sample. The sample is left without further interference for a period of 1 minute.

- 5 Following the 1 min. waiting period a perspex block (1 cm thick with dimensions 8.5 cm x 8.5 cm) is placed on top of the test sample and a weight is lower gently onto the total assemble for a period of 5 minutes. The total pressure exerted onto the test sample, at this point, is 70 g/cm².
- 10 The weight and perspex block is removed and carefully the topsheet sample is removed and placed on a stack of 2 sheets (with dimensions 12 cm x 12 cm) of commercially available filter/blotting paper {produced by Cartiera Favini S.p.A. Italy; Type Absorbente Bianca "N30" (local vendor Ditta Bragiola SpA. Perugia, Italy)) that have been pre-weighed. A second
- 15 stack of 2 pre-weighed filter papers are placed on top of the topsheet sample. A second weight is placed on top of the filter paper stack containing the topsheet sample. The second weight exerts a pressure onto the filter paper stack of 130 g/cm² for a period of 15 seconds. The weight (for this critical step) is attached to a hydraulic arm. The lowering of the
- 20 weight and time the sample is placed under pressure is controlled via a simple electronic device to ensure reproduceability from one test to the next.

- The second weight is removed and each (lying above and below the
- 25 topsheet sample) filter paper stack is weighed and the difference for each surface (liquid pick-up from the topsheet sample) recorded. Materials that have a zero pick-up value for the top surface (placed normally in contact with the users skin) are given a zero "*topsheet retention*" value independent of having a non-zero value for the bottom surface as these
 - 30 materials clearly demonstrate non-communication between the upper and lower surfaces.

Test Solution: Preparation of Test Solution Paper Industry Fluid (PIF)

- 35 The test solution PIF is a widely used test liquid in the Paper industry due to its simple composition, ability to pr pare and maintain high standards of

solution quality and its similarity to human menses with respect to viscosity and ionic surface tension.

5 The solution PIF is prepared by dissolving the following reagent components, at the indicated quantities, into 1 litre of distilled water. Care should be taken in dissolving the solid components and particularly the Carboxymethyl- cellulose. Typically the solid components should be added over a period of one hour slowly and with constant stirring of the solution (via a magnetic stirring device).

20

Representative topsheet examples:

Representative topsheet samples commonly used in hygienic articles and available from a range of companies have been tested and the results are
25 detailed in the attached Table .

Material Sample Type (supplier and material code)	Topsheet Retention (g)	
Example 1: CPM	Top Surface	= 0.00
Supplier Code: X-1522	Bottom Surface	= 0.09
Tredegear Film Products B.V. Holland	Topsheet Retention	= 0.00 *
Example 2: CPT (LDPE)	Top Surface	= 0.00
Supplier Code: 15112	Bottom Surface	= 0.09
Tredegear Film Products B.V. Holland	Topsheet Retention	= 0.00 *
Example 3: Hydrophillic Thermally Bonded Nonwoven	Top Surface	= 0.10
Supplier Code: NW/ThBo/Hy	Bottom Surface	= 0.16
Pantex s.r.l (Italy)	Topsheet Retention	= 0.26
Example 4: Pantex Hydrophobic	Top Surface	= 0.09
Supplier Code: Pantex (PT2)	Bottom Surface	= 0.11
Pantex s.r.l (Italy)	Topsheet Retention	= 0.20
Example 5: Amoco Nonwoven	Top Surface	= 0.09
Supplier Code: Amoco P8	Bottom Surface	= 0.09
Amoco GmbH, Germany	Topsheet Retention	= 0.18

*3-D aperatured films do not allow moisture on the bottom surface to migrate to the top surface as evidenced by the top surface value hence zero is recorded for the value of moisture in contact with the skin.

Vapour and Air Permeability test: Absorbent core

The air permeability test is utilised to assess the ability of the absorbent core to exchange/circulate vapour and preferably air and is carried out on the core material as detailed for an absorbent article.

Representative absorbent core examples:

The air/vapour permeability of representative examples of absorbent core elements has been assessed. The absorbent core have been

manufactured under normal manufacturing procedures by P & G Pescara Technical Centre (Italy) or removed from available market products.

Example 1:

- 5 The core material is a tissue laminate (20 cm x 6.5 cm) composed of a folded stack 2 layers of airlayed tissue of 63 g/m² basis weight (available from Walkisoft USA under the supplier code Metmar (P50W.IPED)). Between the two tissue layers the laminate contains AGM (available from Shokubai Japan under the supplier code; Aqualic L-74 Optimised) at a basis weight of 50 g/m² and has a caliper of 2.2mm.
- 10

Example 2:

- The core is an airfelt structure composed of 80% airfelt and 20 % Bi-Component fibres (PE/PP) produced on a DanWeb (Aahrus, Denmark) thermal bonded airlayed line. The sample (20 cm x 6 cm) has a total basis weight of 120 gsm and has a caliper of 3 mm.
- 15

Example 3:

- Is an absorbent core removed from a market product (Silhouette Ultra, Normal Plus size produced by Johnson & Johnson Montreal, Canada. The package contained the following manufacturing code: 51564 19:23) product. The absorbent core is a multi layer laminate structure composed of tissue like layers and containing a peat moss strip. The absorbent core has a caliper of approximately 3 mm.
- 20

25 Example 4:

- Is an absorbent core removed from a market product (Kotex Ultra Plus Normal produced by Kimberly Klark GmbH Germany The package contained the following manufacturing code: 5178U13:38) product. The absorbent core/structure is a multi layer laminate structure composed of tissue like layers and containing an additional aperatured strip within the core. The absorbent core has a caliper of approximately 4 mm.
- 30

Examples	Caliper	Vapour Permeability	Air Permeability

<u>Example 4:</u> Absorbent Core market product	~4	1350	780

Liquid Permeability Test: Backsheet

- 5 The liquid permeability test is utilised to quantify the barrier properties of breathable backsheet materials or constructions that could be utilised on a breathable absorbent article and particularly on a sanitary napkin.

Basic Principle of the Methods:

10

- The basic principle of the test is to evaluate the performance of backsheet materials or constructions to liquids which simulate bodily discharges. A "good backsheet layer or construction" is expected to be sufficiently open to be classified as breathable but, without being too open to the passage of
- 15 bodily discharges. To ensure that this test is sufficiently representative to the situation when the absorbent article is actually used a test solution closely resembling human menses is utilised, referred to herein as Artificial

Menstrual Fluid (AMF). AMF is based on modified sheeps' blood as detailed in the solution preparation method detailed below.

5 To determine the liquid permeability of a backsheet or backsheet construction, a standard absorbent structure with the backsheet material or construction is prepared and placed flat on a see through test stand made of perspex. The sample to be tested is oriented with the absorbent structure exposed (upper side) and the breathable backsheet side in contact with the perspex test stand (bottom side). Suspended above the
10 sample to be analysed is a liquid delivery system that is capable of delivering any desired quantity of the test liquid.

The standard absorbent structure is composed of 4 layers (folded as a stack) of airlayed tissue of 63 g/m² basis weight {available from Walkisoft
15 USA under the supplier code Metmar (P50W.IPED)} having dimensions of 20 cm x 6.5 cm. The backsheet is then placed on top of this structure without any additional adhesive attachment.

20 Located between the back most surface of the test sample and the see through test stand are two sheets of absorbent filter paper {produced by Cartiera Favini S.p.A. Italy; Type Absorbente Bianca "N30" (local vendor Ditta Bragiola SpA. Perugia, Italy)}. The absorbent filter paper is in intimate contact with the backsheet of the test sample to simulate, for example a sanitary napkin attached to a panty or a diaper/incontinence device in
25 close contact with the clothing. Directly below the see through test stand is a mirror so positioned to allow any red colour change in the absorbent filter paper to be continuously observed. For example, if the backsheet is unable to adequately resist liquid transmission then the filter paper will become wet with the red AMF solution and this can be observed in the mirror. The
30 magnitude of the transmitted solution is determined by simply weighing the absorbent filter paper.

The test solution is introduced to the test sample via a calibrated delivery system such as via a simple burette according to the desired test approach
35 as detailed below. The loading of the pad follows in a step wise manner as typically occurs in-use. Once loaded the test sample is then placed under a pressure of 70 g/cm² which is believed to reflect more stressful pressures

that are nevertheless regularly obtained in-use. The test sample remains under the 70 g/m² pressure for a period of up to 5 mins. At which time the weight is removed and the absorbent filter paper is weighted to determine if and to quantify the extent of liquid that has been transported through the backsheet or backsheet construction.

The process is then repeated entirely with an additional introduction of liquid to the test sample. For each introduction of liquid a new stack of absorbent filter papers (pre-weighted) is used to be able to better determine the liquid barrier behaviour as a function of the load.

The loading steps are specifically:

- | | |
|-------------|---|
| Step 1 | 5 ml |
| Step 2 | 1 ml |
| Step 3 - 11 | 1 ml additions each step to a total loaded volume of 15 ml. |

A good backsheet layer or layered construction is expected to have zero wet-through (absorbent filter paper remains clean and white and does not change weight) throughout the entire stepwise loading program (i.e. until 15 ml load).

Preparation of Test Liquid AMF

Artificial Menstrual Fluid (AMF) is based on modified sheep's blood that has been modified to ensure it closely resembles human menstrual fluid in viscosity, electrical conductivity, surface tension and appearance. In addition we introduce a surfactant (1%) to this test fluid (supplied by by Pegesis/USA) to better reflect stress situations in which typical hygiene practice (and in some limited situations, dietary influences) may introduce additional surfactants or unexpected levels of, for example, fatty acids, that might lower the blood surface tension. Low surface tension menses is the biggest contributor to through backsheet wet-through failure on a breathable absorbent article such as a sanitary article.

Reagents:

- 1) Difibrinated sheep's blood is available from Unipath S.p.A {Garbagnate Milanese/Italy}.
- 2) Lactic Acid from J.T. Baker Holland Reagent Grade (85-95%w/w).
- 3) Potassium Hydroxide (KOH) from Sigma Chemical Co. USA, Reagent grade
- 4) Phosphate Buffer Saline Tablets from Sigma Chemical Co. USA, Reagent grade
- 5) Sodium Chloride from Sigma Chemical Co. USA, Reagent grade
- 6) Gastric Mucine from Sigma Chemical Co. USA, Type III (CAS 84082-64-4)
- 7) Distilled Water.

Step 1:

- Prepare a 9 ± 1 % Lactic Acid Solution by dissolution of lactic acid powder and distilled water.

Step 2:

Prepare a 10% Potassium Hydroxide (KOH) solution by dissolving KOH powder into distilled water.

Step 3:

- Prepare a Phosphate buffer solution buffered to pH = 7.2. by dissolving tablets as directed into 1 L distilled water.

Step 4:

Prepare and slowly heat to 45 ± 5 °C a solution of the following composition:

- o 460 ± 5 ml of phosphate buffer solution
- o 7.5 ± 0.5 ml of KOH solution

Step 5:

- Prepare a Mucous Solution by slowly dissolution (with constant stirring) of approximately 30 grams of gastric mucine in the pre-heated (45 ± 5 °C) solution prepared in step 4. Once dissolved the solution temperature should be increased to between 50 - 80 °C and the mixture covered for approximately 15 mins. Turn the heat down to maintain a relatively constant temperature between 40 and 50 °C and continue to stir for a period of 2.5 hrs.

- Step 6:

Remove the solution from the hot plate and allow the solution (from step 5) to now cool to less than 40 °C. Add 2.0 ml of the 10% lactic acid solution and mix thoroughly for 2 mins.

Step 7:

- 5 Place the solution in an Autoclave and heat to a temperature of 121 °C for 15 mins.

Step 8:

Allow the solution to cool to room temperature and dilute 1 to 1 with the di-fibrinated sheep's blood.

10

- Following AMF preparation its viscosity, pH and conductivity are measured to ensure the blood characteristics lie in a range close to that of normal menstrual blood {(see reference H.J. Bussing "zur Biochemie de Menstrualblutes" Zbl Gynaec, 179,456 (1957))}. The viscosity should lie in the range of 7 to 8 (units cStK). The pH should lie in the range of 6.9 to 7.5 and the conductivity in the range 10.5 to 13 (units mmho). If the viscosity is not within the range specified above it should not be used and a new batch of AMF needs to be prepared. This may require adjustment to the quantity of gastric mucine used. Since this is a natural product its composition may alter from one lot to another.
- 15
- 20

- For individual measurements typically 100 ml AMF test solution with surfactant is prepared by mixing 90 ml AMF solution (maintained at 25 °C) with 10 ml Surfactant. The AMF/1% surfactant solution must be constantly mixed to ensure the components do not separate prior to usage. The solution should be used only within 4 hours of preparation.
- 25

Backsheet Examples:

30 Example 1:

In this example a backsheet currently incorporated in Always Ultra (normal size) available from Procter & Gamble Pescara Technical Centre was tested. The backsheet supplied by Clipay USA (under supplier code DH215 peach) is not a breathable backsheet.

35

Example 2a:

The backsheet is a multi-layer construction composed of two layers. The first layer that is placed directly in contact with the absorbent tissue layer is a formed apertured film (CPT) made of Low Density PE (supplied by Tredegar Film Products B.V. Holland under the manufacturing code X-1522). The bottom most layer that would lie, in-use, directly in contact with the wearers panty is composed of a nonwoven laminate (14MB/14SB manufactured by Corovin GmbH in Germany under the trade name MD 2005). The nonwoven laminate is composed of 14 g/m² spunbond and 14 g/m² meltblown.

10 Example 2b:

The backsheet is comprised of two layers. The first layer is a formed apertured film made of a blend of low and high density PE with a crush resistant hexagonal hole configuration (supplied by Tredegar Film Products B.V. Holland under the manufacturing code AS 225 MD 25). The second layer is an improved nonwoven laminate composed of 3 layers with basis weights 14g/m² spunbond - 20 g/m² meltblown - 14 g/m² spunbond (manufactured by Corovin GmbH in Germany under the trade name MD 3005).

Example 3a:

20 This is also an example of a 2 layer backsheet construction. The first layer that is placed directly in contact with the absorbent tissue layer is a formed apertured film (CPT) made of Low Density PE (supplied by Tredegar Film Products B.V. Holland under the manufacturing code X-1522). The second garment facing layer is composed of a simple microporous film (supplied by Exxon Chemical Company under the manufacturing code Exxaire XBF-101W).

Example 3b:

30 This is also an example of a 2 layer backsheet construction. The first layer that is placed directly in contact with the absorbent tissue layer is a formed apertured film made of a blend of low and high density PE with a crush resistant hexagonal hole configuration (supplied by Tredegar Film Products B.V. Holland under the manufacturing code AS 225 MD 25). The second garment facing layer is composed of a simple microporous film (supplied by Exxon Chemical Company under the manufacturing code Exxaire XBF-102W).

Exempl 4:

In this example a single backsheet layer is utilised. The layer is a laminated nonwoven structure composed of a Polyethylene nonwoven (supplied by Corovin Germany under the code HDPE #17870) onto which a uniform layer (0.8 mil / $\sim 20\text{g/m}^2$) of DuPont Hytrel (supplied by DuPont Corporation, USA) polyester-based film has been co-extruded. (this material was manufactured at request of P & G Cin./USA by Clopay USA under the trial code P18-3097 / 0.8).

Example	Liquid Permeability (g)				
	7 ml	9 ml	11 ml	13 ml	15 ml
Example 1	zero	zero	zero	zero	zero
Example 2a	zero	zero	0.20	0.41	0.55
Example 2b	zero	zero	zero	zero	zero
Example 3a	zero	zero	zero	0.06	~0.16
Example 3b	zero	zero	(commensal) zero	zero	~ zero
Example 4	zero	zero	zero	zero	(commensal) zero

Absorbent article tests

- 5 The following tests were carried out on selected exemplified absorbent articles detailed below:

Representative examples:

- 10 Representative examples of sanitary napkins incorporating a breathable backsheet and manufactured under normal manufacturing procedures by Procter & Gamble Pescara Technical Centre (Italy) SpA. An additional market product that does not feature a breathable backsheet has been included to provide a comparison of products representative of current
15 technology.

Example 1:

- 20 In this example currently available Always Ultra (normal size) market product was tested. The product was manufactured according to normal manufacturing procedures by Procter & Gamble Pescara Technical Centre (Italy) SpA. The topsheet corresponds to the topsheet exemplified in

example 1 of the top sheet examples and the core corresponds to the core exemplified in example 1 of the core examples. The backsheet on this product is not a breathable backsheet.

5 Example 2a:

In this example the backsheet of example 1 is replaced by a backsheet that is a multi-layer construction composed of two layers. The first layer that is placed directly in contact with the absorbent core is a formed apertured film (CPT) made of Low Density PE (supplied by Tredegar Film Products B.V. Holland under the manufacturing code X-1522). The bottom most layer that would lie, in-use, directly in contact with the wearers panty (garment facing layer) is composed of a nonwoven laminate (14MB/14SB manufactured by Corovin GmbH in Germany under the trade name MD 2005). The nonwoven laminate is composed of 14 g/m² spunbond and 14 g/m² meltblown. The inter element glue attachment to connect the first backsheet layer (apertured film) to the absorbent core is typical and extensively practiced. The core and apertured backsheet layer is attached via two slot coated layers (at about 8 g/m²) of adhesive (each 20 mm wide and 170 mm long and separated by a 11 mm gap) forming a relatively impermeable zone where the materials are joined. The second nonwoven backsheet layer is joined over the full surface of the first backsheet layer by a spray glue application at a basis weight of approximately 10 g/m². The glue utilised for attachment of both backsheet layers was supplied by SAVARA SpA. Italy (under the material code PM17). The attachment of the product to the panty is provided for by two stripes of adhesive (material code Lunatak HL-2238 X supplied by Fuller GmbH, Germany). The stripes are 170 mm long, each is 22 mm wide and a gap of 11 mm exists between the stripes which are centered both length and breadthwise on the article. The backsheet element does meet the backsheet liquid permeability requirements of the present invention.

Example 2b:

This example is similar to that of example 2a except the formed apertured film backsheet layer is a blend of low and high density PE with a crush resistant hexagonal hole configuration (supplied by Tredegar Film Products B.V. Holland under the manufacturing code AS 225 HD 25). The second backsheet layer is also an improved nonwoven laminate composed of 3

layers with basis weights 14g/m² spunbond - 20 g/m² meltblown - 14 g/m² spunbond (manufactured by Corovin GmbH in Germany under the trade name MD 3005). In addition the inter layer/element glue attachment has been optimised to enhance both the articles flexibility and breathability. The inter-layer gluing design is a low basis weight (6 g/m²) spiral glue pattern (2 spirals each 10 mm wide and 160 mm long separated by 20 mm). This gluing design is used to connect the first backsheet layer (apertured film) to the absorbent core. The attachment of the second backsheet layer is via low basis weight spiral glue application only at the perimeter of the product. A glue free window of approximately 40 mm wide and 170 mm long and centered in the product is used to enhance the pad flexibility. The glue utilised for attachment of both backsheet layers was supplied by SAVARA SpA. Italy (under the material code PM17).

Example 2c:

This example is identical to that of example 2b except the application of the panty fastening adhesive (PFA) has been optimised to enhance breathability without compromise of adhesive functionality. The two stripes of panty fastening adhesive that is detailed in Example 2a has been replaced by a matrix of PFA dots designed to enhance the backsheet openness without changing the overall physical dimensions. With the application of a dot pattern, rather than a slot application of adhesive, the surface over which the PFA adhesive is applied is approximately 30 % free from adhesive.

Example 3a:

This example is identical to example 1 wherein the backsheet has been replaced by a 2 layer backsheet construction. The first layer backsheet that is placed directly in contact with the absorbent tissue core is a formed apertured film (CPT) made of Low Density PE (supplied by Tredegar Film Products B.V. Holland under the manufacturing code X-1522). The second backsheet layer that would lie, in-use, directly in contact with the wearers panty is composed of a simple microporous film (supplied by Exxon Chemical Company under the manufacturing code Exxaire XBF-101W). The inter layer/element glue attachment of the backsheet layers and the backsheet and core is based on slot application as described in example 2a. The backsheet element does not meet the requirements of the

backsheet liquid permeability and thus this absorbent article is not representative of the present invention.

Example 3b:

- 5 This example is identical to example 3a except that the formed apertured film backsheet layer is a blend of low and high density PE with a crush resistant hexagonal hole configuration (supplied by Tredegar Film Products B.V. Holland under the manufacturing code AS 225 HD 25) and the microporous film is supplied by Exxon Chemical Company under the
10 manufacturing code Exxaire XBF-102W}. Furthermore, the inter layer/element glue attachment has been optimise to enhance both the articles flexibility and breathability. The inter-layer/element gluing design is a low basis weight (6 g/m^2) spiral glue pattern (2 spirals each 10 mm wide and 160 mm long separated by 20 mm). This is used to connect both the
15 first backsheet layer (aperatured film) to the absorbent core and the second microporous film backsheet layer to the first backsheet layer (the aperatured film). The second backsheet layer is also attached at the perimetry by a temperature/pressure fusion process (crimp) as utilised in the current Always market product in Europe. The glue utilised for
20 attachment of both backsheet layers was supplied by SAVARA SpA. Italy (under the material code PM17).

Example 3c:

- 25 This example is identical to that of example 3b except the application of the PFA has been optimised to enhance breathability without compromise of adhesive functionality. Specifically the two stripes of panty fastening adhesive that is detailed in Example 2a has been replaced by a matrix of PFA dots as detailed in example 2c, designed to enhance the backsheet openness.

30

Example 4a:

- This example is identical to example 1 except that the backsheet has been replaced by a single layer laminated nonwoven structure composed of a Polyethylene nonwoven (supplied by Corovin Germany under the code
35 HDPE #17870) onto which a uniform layer ($0.8 \text{ mil} / \sim 20 \text{ g/m}^2$) of DuPont Hytrel (supplied by DuPont Corporation, USA) polyester-based film has been co-extrud d. (this material was manufactured at request of P & G

Cin./USA by Clopay USA under the trial code P18-3097 / 0.8). The backsheet is joined to the core using a low basis weight (6g/m) spiral glue pattern (2 spirals each 10mm wide and 160mm long separated by 20mm).

5 **Example 4b:**

This example is identical to that of example 4a except the application of the PFA has been optimised to enhance breathability without compromise of adhesive functionality. Specifically the two stripes of PFA normally applied has been replaced by a matrix of PFA dots designed to enhance the
10 backsheet openness as detailed in example 2c.

Example 5a:

In this example a market product has been assessed; The product, Silhouettes Ultra (normal plus size) Manufactured by Johnson & Johnson,
15 Montreal Canada (Print code on bag; 51564 19:23) and Imported into Italy by Johnson & Johnson Roma. The product does not contain a breathable backsheet and does not meet the requirement of the elements or the absorbent article requirements and is thus not representative of the present invention.

20

Air & Vapour Permeability Test on absorbent article products

The Vapour permeability test is utilised to quantify the vapour transmission properties of breathable absorbent articles.

25

Basic Principle of the Methods:

The basic principle of the test is to quantify the extent of water vapour transmission of an absorbent article. The test method that is applied is
30 based on a standardized textile industry applied test method and commonly referred to as the "cup test method". The test is performed in a stable temperature/humidity laboratory maintained at a temperature of 23° C at 50% RH for a period of 24 hours.

35 **Apparatus:**

- 1) Sample cup of dimensions specified in the drawing (open area = 0.00059 m^2)
- 2) Syringe to introduce the distilled water into the completed sample cup.
- 5 3) Wax to seal the cup once sample has been arranged.
- 4) A circular punch to facilitate preparation circular samples of diameter = 30 mm.
- 5) Laboratory of stable climatic conditions ($23^\circ \text{ C} \pm 0.5^\circ \text{ C}$ / $50\% \text{ RH} \pm 1\% \text{ RH}$)
- 10 6) Laboratory balance accurate to 4 decimal places.

Sample Preparation / Measurements:

15 The test is performed on the absorbent article product. A representative article is selected and a sample is cut to size using the punch. The sample cut is sufficiently large to adequately overlap the sample holder and to ensure material that may have been damaged or undesirably stretched due to the cutting operation lies outside of the measurement centre when the measurement is performed. The sample is so arranged onto of the sample
20 cup so as to fully overlap the cup. The sample is oriented so as to ensure that the surface exposed to the laboratory environment is the same that would be found while wearing the article.

25 The closure ring of the sample cup is then placed onto the sample and pushed down. This ensures that the excess material is held firmly in place and does not interfere with the measurement. A wax is then applied to the entire surface of the closure ring to ensure the whole upper part of the apparatus is closed to the environment. Distilled water ($5 \pm 0.25 \text{ ml}$) is introduced with the syringe into the sealed sample cup via the minute
30 perforation. Finally this perforation is sealed with silicone grease.

The entire cup (containing sample and water) is weighed and the weight recorded to 4 decimal places. The cup is then placed in a ventilation stream generated by a fan. The air flowing over the top of the sample cup
35 is $3 \pm 0.3 \text{ m/sec}$ and confirmed via a wind velocity meter ("Anemo", supplied by Deuta SpA., Italy). The sample cup remains in the ventilated test field for a period of 24 hrs and is then re-weighted. During this period if the test

sample is sufficiently breathable the liquid in the sample holder is able to diffuse out of the sample holder and into the laboratory environment. This results in a reduction in the weight of water in the sample holder that can be quantified on re-weighing the complete sample cup following the 24 hr period.

The vapour permeability value is determined as the weight loss divided by the open area of the sample holder and quoted per day.

i.e. Vapour Permeability = Weight Loss (g) / (0.00059 m²/ 24 hrs)

Air Permeability test:

The air permeability test is utilised to assess the ability of an absorbent structure to circulation/exchange air.

Basic Principle of the Methods:

The basic principle of the test is to evaluate the resistance of an absorbent article to the passage of air. In this test, the volume (or amount) of air that flows through an article of given dimensions under standard conditions (of 23 °C /50% RH) is measured. The instrument utilised for the test is: Air Permeabilimeter FX 3300 manufactured by TexTest AG Switzerland.

Samples should be allowed to equilibrate in the test environment for at least 4 hrs prior to commencement of the measurement. The article (having dimensions exceeding 5 cm² the dimensions of the measurement head) is placed on the device as instructed by the manufacturer. An aspiration pump set to generate a pressure of 1210 kPa that sucks air through the sample layer or structure. The device measures the volume of air flow and the pressure drop across the orifices that contains the sample and measurement head. Finally the device generates a value of air permeability in the units of "l/m²s⁻¹".

In the case of vapour and air permeability measurements on a finished product the area of Panty Fastening Adhesive (PFA) can influence the results particularly if the adhesive is applied as is typically the case as an

impervious stripe of adhesive via a slot coater. The measurements of both air and vapour permeability need to be representative of the total product. One simple way to ensure a representative measurement is to assess backsheet samples with some PFA coverage. For example in the case of
5 Example 2a,b Example 3a,b, and Example 4 a,b the total backsheet area is covered to a degree of 45% with PFA. The vapour and air permeability measurements are thus performed on the samples featuring a 45% surface coverage by PFA adhesive.

10 **Rewet Test:**

The rewet test applied here is well detailed is the standard P & G applied copy claim rewet test method that forms the basis of our claim support for dryness.

15

Basic Principle of the Methods:

In this context the rewet method is utilised to assess the dryness of the product with respect to the wearer facing surface of the product . In
20 combination with additional test methods that assess the dryness of the product with respect to the openness of the backsheet (air & vapour permeability test) it allows the total product dryness to be represented.

The test solution that is utilised for this test is based on the Paper Industry Fluid (PIF) that has been extensively utilised (due to its stability and high reproducibility) and due to its close similarity to human menses in terms of
25 viscosity and liquid surface tension & ionic strength. The solution preparation is detailed below.

30 **Apparatus:**

- 1) Blotting Paper available from Schleicher & Schuell (Germany).
S & S Rundfilter / Durchmesser 150 mm, No. : 597, Reference-No.: 311812.
- 2) A weight of 4200 g covered on the lower surface with a foam of
35 moderate flexibility. Both the weight and foam are covered with a thin, flexible plastic film to maintain waterproofs. The weight dimensions

should allow a 6 cm x 10 cm surface to contact the article under examination. Pressure exerted onto the article = 70 g/cm².

- 3) A perspex (7 mm thick) plate of dimensions 6 cm x 10 cm with a hole of dimensions 3 cm x 4 cm centred in the template.
- 5 4) A burette capable of introducing the test fluid at a reproducible rate of 7 ml in 90 seconds.
- 5) An analytical balance capable of reading to 4 decimal places.

Sample Preparation / measurement:

10

The article to be assessed is removed from an packaging and placed on a flat laboratory surface and centred directly below the burette for test liquid delivery. The perspex plate is placed on the surface and the PIF test liquid is introduced over the exposed area corresponding to the hole in the perspex plate. After 90 seconds 7 ml of PIF have been introduced to the sample and an electronic counter set to 20 min's is activated. During this waiting period a stack of 7 discs of filter paper are weighed on the analytical balance and noted.

- 20 After 20 mins. the perspex plate is removed and the stack of filter papers are positioned centrally on the article being assessed and the weight is gently lowered onto the filter paper stack. The article and filter paper stack remain under the pressure exerted by the weight for a period of 15 seconds, after which the weight is carefully removed and the filter paper stack is re-weighted. The difference in weight (to the nearest milligram) is recorded as the rewet value. The tests are repeated for at least 10 samples to ensure adequate accuracy of the measurements.

Flexibility Test & Caliper Test:

30

Basic Principle of the Methods:

- 35 The flexibility test is utilised to quantify the product flexibility or product stiffness in the cross direction. Most flexibility tests have attempted to establish a product benefit based on a product design change using a range of flexibility test methods to quantify this such as measuring the drap (bend ability) of a product or the combination of stiffness in both

length and cross direction. The flexibility test used herein is a dynamic stiffness measurement (force to deform vs. distance deformed) which determines the resistance of a product to deform in the cross direction. The higher the stiffness value the more the product is likely to push against the sensitive skin of the wearers inner thighs and create a sensory negative during various bodily motions.

Apparatus:

10 **1) Climatically controlled Lab.**

Maintenance of 23 °C and 50 % Relative humidity.

2) Instron Limited, UK Model 6021

Interfaced to a standard IBM with RS 232 interface for data logging.

15 Data are sent to the IBM computer in the form of distance and force values.

Data is read into a standard Microsoft Excel worksheet for analysis.

Load cell = 10 N

Initial clamp separation = 55 mm

20 Final clamp separation = 25 mm

Distance sample to be deformed = 30 mm

Compression speed = 25 mm / 1 mins.

25 **3) Caliper Measurement Device: Mitutoyo Instruments (Japan) Model 543 - 601 B**

The caliper is measured using a precision digital measurement device (± 0.02 mm) with a circular measurement foot of 40 mm diameter that exerts a pressure of 6.2 g/cm^2 .

30

Sample Preparation:

The tests are performed on the final form of the product identical in all ways and preferably on the same batch of products to be worn or assessed by a consumer.

35

In the case of a sanitary napkin, or light incontinence device the product is removed from packaging and any release paper that may be used to maintain adhesives used to attached the article to a panty or other piece of clothing is be removed. Exposed glue surfaces (i.e. panty fastening adhesive) are rendered inactive by lightly applying a talcum powder to the adhesive surface.

Caliper Measurement:

The Average caliper of the products is first determined. For products that are inherently flat the caliper at representative points (at least 5) of the product is measured to determine an average value. For products of complex shapes, such as relatively thick in the centre and relatively thin in the extremities, a smaller measurement foot on the caliper device (maintaining a measurement pressure of 6.2 g/cm^2) is used and to ensure at least 10 measurement points are utilised to more accurately determine the average product thickness.

Flexibility Measurement

The product is attached vertically between the clamps of the Instron device. The clamps are so positioned to start the compression (in product cross direction) from a distance of 55 mm. The sample is compressed over a distance of 30 mm to a final clamp separation of 25 mm. The instrument details are given above.

The Instron records the clamp separation (in mm) and the force exerted to achieve this separation and send this data via an RS232 interface to an IBM computer equipped with Microsoft windows 3.1 and Microsoft Excel version 4.0. The force and distance data are loaded in to the Excel software and the average force measurements over the full 30 mm compression cycle is determined.

The measurements are performed on 10 samples of the same type to ensure a representative stiffness value to be determined for the sample under investigation.

The caliper of various core material are indicated under the core measurement table results. The results of caliper and flexibility test for a number of absorbent article test products are given under the sensory index.

5

Sensory Index:

The sensory index is a quantitative value that reflects how a product design impacts sensory perception.

- 10 The sensory index is determined from the ration of;

$$\text{Effective Breathability} / \text{Product Flexibility} \times \text{Product Caliper}$$

- 15 To determine the sensory index value the following 3 tests are to be performed on the final product:

- 1) Effective Breathability Test .
- 2) Product Flexibility Test
- 3) Product Caliper Test

20

E.g	Caliper (mm)	Flexibility (N)	VP (g/m ² /24hr)	AP (l/m ² /s)	Effective Breath- ability	Sensory Index
1	2.7	0.35	zero	zero	zero	zero
2a	2.7	0.75	670	525	801	395
2b	3.0	0.33	790	800	990	1000
2c	3.0	0.32	930	1005	1181	1230
3a	2.8	0.85	495	zero	495	207
3b	2.9	0.36	630	zero	630	603
3c	2.9	0.35	844	zero	844	832
4a	2.8	0.32	590	zero	590	658
4b	2.8	0.32	660	zero	660	737

42						
5a*	~3	1.5	zero	zero	zero	zero

VP= Vapour permeability

AP= Air permeability

* = market product unmodified

5

Dryness Index:

The dryness index is determined from the ratio of;

10 **Effective Breathability / Product Wetness (Rewet)**

To determine the dryness index value the following two tests are to be performed on the final product:

- 15 1) Effective Breathability Test
 2) Product Wetness (Rewet) test

E.g.	Rewet (mg)	Permeability Vapour (g/m ² /24hr.)	Permeability Air (l/m ² /sec)	Effective Breathability	Dryness Index
1	50	zero	zero	zero	zero
2a	51	670	525	801	16
2b	50	790	800	990	20
2c	50	930	1005	1181	24
3a	50	505	zero	505	10
3b	50	630	zero	630	13
3c	50	844	zero	844	17
4a	50	590	zero	590	12
4b	50	660	zero	660	13
5a	57	zero	zero	zero	zero

Of the above results for the exemplified absorbent articles, absorbent
 5 article examples 1 and 5a do not meet the sensory or dryness indexes.

Examples 2a and 3a are not demonstrative of the present invention as they
 do not meet the backsheet permeability requirements and thus do not
 provide the required level of protection.

10

Examples 2b, 2c, 3b, 3c, 4a, and 4b are representative examples of the
 present invention. The increase in the sensory and dryness indexes by the
 use of the preferred joining system of spiral spraying adhesive and the
 preferred panty fastening system can be seen from the values of 3b to 3c
 and 4a to 4b.

15

In preferred embodiments of the present invention the absorbent article
 should preferably meet at least one of the requirements of vapour

perm ability, air premeability, flexibility, caliper and rewet such that the article has:

- 5 - a vapour permeability of greater than $100\text{g/m}^2/24\text{hrs}$, preferably greater than $300\text{g/m}^2/24\text{hrs}$, more preferably greater than $500\text{g/m}^2/24\text{hrs}$, most preferably greater than $700\text{g/m}^2/24\text{hrs}$, as defined in the absorbent article vapour permeability test.
- an air permeability of greater than 100, preferably greater than 250, more preferably greater than 500, most preferably greater than $600\text{l/m}^2/\text{s}$, as defined in the absorbent article air permeability test,
- 10 - a flexibility of less than 1.5N, preferably less than 1.0N, more preferably less than 0.7N, most preferably less than 0.5N, as defined in the flexibility test,
- a caliper of less than 12mm, preferably less than 9mm, more preferably less than 6mm, most preferably from 5mm to 2mm,
- 15 - a rewet of less than 500mg., preferably less than 300mg., more preferably less than 200mg., most preferably less than 100mg as defined in the absorbent article rewet test.

CLAIMS

5

1. A disposable absorbent article comprising the following elements:

10

a liquid pervious topsheet, an absorbent core and a breathable backsheet, said absorbent core being positioned intermediate said topsheet and said backsheet, said topsheet, core and backsheet each comprising at least one layer,

15

wherein said topsheet has a liquid retention of less than 0.22g for a 2.0g load in the topsheet liquid retention test, wherein said core has a caliper of less than 12mm and has a vapour permeability of at least 200g/m²/24hrs. as defined in the vapour permeability test and, wherein said breathable backsheet has a liquid permeability of less than 0.16g for a 15ml. load as defined in the liquid permeability test, and

20

wherein said elements are joined such that said absorbent article has a dryness index of greater than 0.5 and a sensory index of greater than 50.

25

2. A disposable absorbent article according to claim 1, wherein each said element has a wearer facing surface and a garment facing surface, each of said garment facing surfaces forming a common interface with an adjacent wearer facing surface of an adjacent element, and wherein said core and said breathable backsheet are joined across less than 40% of the common interface of said garment facing surface of said core and said wearer facing surface of said breathable backsheet.

30

35

3. A disposable absorbent article according to claim 2, wherein said core and said breathable backsheet are joined across less than 20% of said common interface of said garment facing surface of said core and said wearer facing surface of said breathable backsheet.

4. A disposable absorbent article according to any one of the preceding claims, wherein said breathable backsheet element comprises at least two layers, wherein each said layer has a wearer facing surface and a garment facing surface, each of said garment facing surfaces forming a common interface with an adjacent wearer facing surface of an adjacent layer, and wherein adjacent layers are joined across less than 40% of said common interface of said adjacent layers.
5. A disposable absorbent article according to claim 4, wherein said adjacent layers are joined across less than 20% of said common interface of said adjacent layers.
6. A disposable absorbent article according to any one of the preceding claims, wherein said wearer facing surface and said garment facing surface forming said common interface are joined by spiral sprayed adhesive or fusion bonding.
7. A disposable absorbent article according to any one of the preceding claims, wherein said garment facing surface of said breathable backsheet has an adhesive fastening means.
8. A disposable absorbent article according to claim 7, wherein at least 60% of said garment facing surface of said backsheet is adhesive free.
9. A disposable absorbent article according to claim 8, wherein at least 80% of said garment facing surface of said backsheet is adhesive free.
10. A disposable absorbent article according to any one of the preceding claims, wherein said topsheet has a liquid retention of less than 0.15g for a 2.0g load in the topsheet retention test.
11. A disposable absorbent article according to any one of the preceding claims, wherein said core has a caliper of less than 8mm.

12. A disposable absorbent article according to any one of the preceding claims, wherein said core has a vapour permeability of greater than $600\text{g/m}^2/24\text{hrs.}$ as defined in the vapour permeability test.
- 5 13. A disposable absorbent article according to any one of the preceding claims, wherein said breathable backsheet has a liquid permeability of less than 0.10g for a 15ml. load as defined in the liquid permeability test.
- 10 14. A disposable absorbent article according to any one of the preceding claims, wherein said absorbent article has a sensory index of greater than 100.
- 15 15. A disposable article according to any one of the preceding claims, wherein said absorbent article has a dryness index of greater than 2.
16. A disposable absorbent article according to any one of the preceding claims, wherein said article has a flexibility of less than 1.5N as defined in the flexibility test.
- 20 17. A disposable absorbent article according to any one of the preceding claims wherein said article is a sanitary napkin.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US97/10032

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) :A61F 13/15

US CL :604/383

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 604/383-385.1, 387

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US97/10032

Box I (Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet))

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☒ Claims Nos.: 6-17
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
☐ No protest accompanied the payment of additional search fees.
